# 1 All Classes

**Boolean reload** [Method on All Classes]  
this method will semantically refresh items, such as Schema objects or rows, depending on the context of the object in question.

## 2 module DBI

**DBH connect** (*Class klass, Array \*args, Proc &block*) [Method on DBI]

class is a ruby class which corresponds to the database driver. it is no longer a string.

\*args is a hash with parameter -> value associations, such as :host or :username.

Optionally yields a block for usage, yields a freshly connected DBH.

**Array of Class drivers** [Method on DBI]

accessor to get at known classes that can be used as drivers.

**DBH connect\_cached** (*Class klass, Array \*args*) [Method on DBI]

connect to a new resource if one is required (or desired, see below) with similar parameters as connect().

additional arguments :pool\_name and :pool\_size can be used to define a Pool (object, see below) which holds a specific subset of connected database handles. Playing with the size here introduces the ability for connect\_cached to maintain a minimum number of connections which can be re-used over the lifetime of a program.

**Pool pool** (*String pool\_name*) [Method on DBI]

a pool as described above is an array of database handles. this returns that data as a "Pool" object, with its own API. See later on in the document.

**Pool all\_connections** [Method on DBI]

similar to pool(), this returns all the connections, but ignores pools.

**Integer ping** (*Class klass, Array \*args*) [Method on DBI]

similar to connect(), this issues a ping to the databases. This may issue a connect() before the ping() to do it properly depending on the database implementation.

**Boolean reconnect\_all** [Method on DBI]

reconnects all the known database handles.

**DBH last\_dbh** [Method on DBI]

returns the last returned dbh from connect() or connect\_cached()

this method, by definition, can be unpredictable in threaded environments.

## 3 class DBH

<b>NilClass</b> <code>transaction</code> ( <i>Proc &amp;block</i> )	[Method on DBH]
opens a transaction and executes the statements in the block. Yields self.	
<b>Schema</b> <code>table_schema</code> ( <i>Symbol table_name</i> )	[Method on DBH]
returns information about a specific table in a Schema object	
<b>Array of Schema</b> <code>schema</code> ( <i>Symbol schema_name</i> )	[Method on DBH]
returns information about a specific schema, the current one if none is specified.	
<b>Boolean</b> <code>reconnect</code>	[Method on DBH]
reconnects to the database	
<b>Integer</b> <code>ping</code>	[Method on DBH]
attempts to contact the database, measuring round-trip.	
<b>Object</b> <code>driver</code>	[Method on DBH]
returns the underlying driver.	
<b>String</b> <code>last_query</code>	[Method on DBH]
returns the last query executed or prepared.	
<b>STH</b> <code>last_sth</code>	[Method on DBH]
returns the last statement handle prepared.	
<b>Mutex</b> <code>mutex</code>	[Method on DBH]
returns the mutex for this database. thread management will be per-dbh.	
<b>String</b> <code>preprocess_query</code> ( <i>String query</i> )	[Method on DBH]
preprocesses the query and returns what it would look like right before it gets sent to the database.	
<b>Boolean</b> <code>disconnect</code>	[Method on DBH]
disconnects from the database. returns success.	
<b>Symbol</b> <code>bind_style</code> ( <i>Symbol of [native, preprocessed] style</i> )	[Method on DBH]
Accessor. Native style delegates to the underlying database connector. preprocessed means we do it.	

### 3.1 Query Methods

these methods all optionally use a block and yield a result or sth depending on context:

<b>Result</b> <code>select</code> ( <i>String query, Array *binds</i> )	[Method on DBH]
performs a query and returns the result.	
<b>Result</b> <code>select_one</code> ( <i>String query, Array *binds</i> )	[Method on DBH]
performs a query and returns the result, only yielding the first set of items.	
<b>STH</b> <code>prepare</code> ( <i>String query</i> )	[Method on DBH]
prepares a query for execution and returns a statement handle.	
<b>Boolean</b> <code>execute</code> ( <i>String query, Array *binds</i> )	[Method on DBH]
blindly executes a query and returns some idea of success.	

## 4 class STH

<b>Result</b> <code>execute (Array *binds)</code>	[Method on STH]
executes the prepared statement. optionally yielding a result if block given.	
<b>Object</b> <code>driver</code>	[Method on STH]
if any, returns the underlying statement handle from the database object.	
<b>Result</b> <code>last_result</code>	[Method on STH]
Returns the last Result this prepared statement has yielded.	
<b>Boolean</b> <code>finish</code>	[Method on STH]
finishes the statement	
<b>DBH</b> <code>dbh</code>	[Method on STH]
returns the dbh this statement handle was created from.	

## 5 class Pool

**Boolean reconnect** [Method on Pool]

attempts to reconnect the entire pool of database connections.

**Integer ping** [Method on Pool]

attempts to ping and average the response time of all database connections.

**Boolean disconnect** [Method on Pool]

disconnects all the database connections in the pool.

## 6 class Result

- Row or Array fetch** (*Integer row\_count*) [Method on Result]  
fetches one row, or given an argument, row\_count rows.
- Row or Array fetch\_all** [Method on Result]  
fetches all rows.
- Object fetch\_struct** (*Class kind, Array \*args*) [Method on Result]  
fetches the rows and attempts to construct a data structure out of them, given a class which can do so. API for that is forthcoming.
- Boolean finish** [Method on Result]  
finishes the underlying statement handle and invalidates the data. reloading will no longer be possible once this is called and should raise (or maybe we should reprepare/execute?).
- STH sth** [Method on Result]  
returns the statement handle that yielded this result.
- Schema schema** [Method on Result]  
returns a Schema object that corresponds to the data in this result.

# Method Index
